Dear Kineto Team,

I build agentic systems that ship and keep working. Here is the evidence.

My Master's thesis is a production agentic pipeline. An autonomous agent (Double DQN, PyTorch) receives a state from a knowledge graph, selects from a six-action repair space, receives structured feedback from formal OWL reasoning systems, updates its state, and iterates until the task is done — fully autonomously, across thousands of test cases. The LLM layer (GPT-4o mini, OpenAI API) handles structured data extraction using engineered prompts that produce consistent, verifiable outputs. I built a quality evaluation workflow to track correctness across violation types, catch regressions, and validate that the system actually improves with training. It achieves 88 to 96 percent task success. That is not a demo. That is a system I designed, built, evaluated, and own.

The failure-handling part is not an afterthought in that system. Action masking prevents the agent from taking invalid actions in a given state. Shaped rewards penalise loops and reward progress. The Human-in-the-Loop protocol exists specifically for the cases where the agent would otherwise get stuck and degrade. Building reliability into agent behaviour rather than bolting it on afterward is something I thought hard about.

On the full-stack side: React.js, Node.js, Express, MongoDB across Fraunhofer IGCV, DFKI, TUM, and Accenture. At Fraunhofer, I shipped a production ML system for live manufacturing — data pipeline, model, API, Docker, deployment, monitoring. At DFKI, I built a real-time platform that researchers used daily. These are not side projects.

What I do not have: LangChain, eval harnesses like Langfuse, or function-calling patterns in the modern agent framework sense. My agent work uses custom orchestration and raw OpenAI API rather than a framework wrapper. I pick up tooling fast when the fundamentals are in place — and they are.

Kineto moves fast, ships early, and measures results. That is how I work. I would like to be part of it.
